

a Replicated poly(A)-site switches, read coverage at the locus

Mean read depth per cell on the gene's strand. Two mice scored independently; each column is one mouse.

Percentages on each track are the tested quantity, proximal % / distal % of the gene's reads in that stage, not read off the coverage.

Gene model: tall blocks coding, low blocks untranslated, line with chevrons intronic and in the direction of transcription. The transcript carrying both sites is drawn dark, other isoforms grey, and the green block is the single 3'UTR that holds both sites.
